KEYS AND ADDRESSES MODULE

class keys.Address(address=None, hash160=None)

Represents a Bitcoin address

hash160

the hash160 string representation of the address; hash160 represents two consequtive hashes of the public key or the redeam script, first a SHA-256 and then an RIPEMD-160

Type str

from_address (address)

instantiates an object from address string encoding

from_hash160 (hash160_str)

instantiates an object from a hash160 hex string

to address()

returns the address's string encoding

to_hash160()

returns the address's hash160 hex string representation

Raises

- TypeError No parameters passed
- ValueError If an invalid address or hash160 is provided.

classmethod from_address(address)

Creates and address object from an address string

classmethod from_hash160 (hash160)

Creates and address object from a hash160 string

to_address()

Returns as address string

network_prefix = (1 byte version number) data = network_prefix + hash160_bytes data_hash = SHA-256(SHA-256(hash160_bytes)) checksum = (first 4 bytes of data_hash) address_bytes = Base58CheckEncode(data + checksum)

to_hash160()

Returns as hash160 hex string

class keys.PrivateKey(wif=None, secret_exponent=None)

Represents an ECDSA private key.

key

the raw key of 32 bytes

Type bytes

from wif(wif)

creates an object from a WIF of WIFC format (string)

to wif(compressed=True)

returns as WIFC (compressed) or WIF format (string)

to_bytes()

returns the key's raw bytes

sign_message (message, compressed=True)

signs the message's digest and returns the signature

sign_transaction (tx, compressed=True)

signs the transaction's digest and returns the signature

get_public_key()

returns the corresponding PublicKey object

classmethod from_wif(wif)

Creates key from WIFC or WIF format key

get_public_key()

Returns the corresponding PublicKey

sign_input (tx, txin_index, script, sighash=1, compressed=True)

Signs a transaction with the private key

Bitcoin uses the normal DER format for transactions. Each input is signed separately (thus txin_index is required). The script of the input we wish to spend is required and replaces the transaction's script sig in order to calculate the correct transaction hash (which is what is actually signed!)

Returns a signature for that input

sign_message (message, compressed=True)

Signs the message with the private key

Bitcoin uses a compact format for message signatures (for tx sigs it uses normal DER format). The format has the normal r and s parameters that ECDSA signatures have but also includes a prefix which encodes extra information. Using the prefix the public key can be reconstructed when verifying the signature.

Prefix values: 27 - 0x1B = first key with even y 28 - 0x1C = first key with odd y 29 - 0x1D = second key with even y 30 - 0x1E = second key with odd y

If key is compressed add 4(31 - 0x1F, 32 - 0x20, 33 - 0x21, 34 - 0x22 respectively)

Returns a Bitcoin compact signature in Base64

to_bytes()

Returns key's bytes

to_wif(compressed=True)

Returns key in WIFC or WIF string

key_bytes = (32 bytes number) [+ 0x01 if compressed] network_prefix = (1 byte version number) data_hash = SHA-256(SHA-256(key_bytes)) checksum = $(\text{first 4 bytes of data_hash})$ wif = Base58CheckEncode(key_bytes + checksum)

class keys.PublicKey(hex_str)

Represents an ECDSA public key.

key

the raw public key of 64 bytes (x, y coordinates of the ECDSA curve)

Type bytes

from_hex (hex_str)

creates an object from a hex string in SEC format

from_message_signature(signature)

NO-OP!

verify_message (address, signature, message)

Class method that constructs the public key, confirms the address and verifies the signature

to_hex (compressed=True)

returns the key as hex string (in SEC format - compressed by default)

to_bytes()

returns the key's raw bytes

get_address(compressed=True))

returns the corresponding Address object

classmethod from_hex(hex_str)

Creates a public key from a hex string (SEC format)

get_address (compressed=True)

Returns the corresponding Address (default compressed)

to_bytes()

Returns key's bytes

to_hex (compressed=True)

Returns public key as a hex string (SEC format - compressed by default)

verify (signature, message)

Verifies a that the message was signed with this public key's corresponding private key.

classmethod verify_message(address, signature, message)

Creates a public key from a message signature and verifies message

Bitcoin uses a compact format for message signatures (for tx sigs it uses normal DER format). The format has the normal r and s parameters that ECDSA signatures have but also includes a prefix which encodes extra information. Using the prefix the public key can be reconstructed from the signature.

Prefix values: 27 - 0x1B = first key with even y 28 - 0x1C = first key with odd y 29 - 0x1D = second key with even y 30 - 0x1E = second key with odd y

If key is compressed add 4 (31 - 0x1F, 32 - 0x20, 33 - 0x21, 34 - 0x22 respectively)

Raises ValueError - If signature is invalid

TRANSACTIONS MODULE

```
class transactions.Transaction(inputs=[],
                                                      outputs=[],
                                                                   locktime=b'x00x00x00x00',
                                         sion=b'x02x00x00x00'
     Represents a Bitcoin transaction
     inputs
          A list of all the transaction inputs
              Type list (TxInput)
     outputs
          A list of all the transaction outputs
              Type list (TxOutput)
     locktime
          The transaction's locktime parameter
              Type bytes
     version
          The transaction version
              Type bytes
     stream()
          Converts Transaction to bytes
     serialize()
          Converts Transaction to hex string
     copy()
          creates a copy of the object (classmethod)
     get_transaction_digest (txin_index, script, sighash)
          returns the transaction input's digest that is to be signed according to sighash
     classmethod copy (tx)
          Deep copy of Transaction
     get_transaction_digest (txin_index, script, sighash=1)
          Returns the transaction's digest for signing.
          SIGHASH types (see constants.py): SIGHASH_ALL
                                                                 SIGHASH_NONE
                                                                                      SIGHASH_SINGLE
              SIGHASH_ANYONECANPAY (only combined with one of the above)
          txin index
              The index of the input that we wish to sign
                  Type int
```

```
script
               The scriptPubKey of the UTXO that we want to spend
                   Type list (string)
           sighash
               The type of the signature hash to be created
                   Type int
     serialize()
          Converts to hex string
     stream()
          Converts to bytes
class transactions. TxInput (txid, txout_index, script_sig=b", sequence=b'xffxffxffxfff')
     Represents a transaction input.
     A transaction input requires a transaction id of a UTXO and the index of that UTXO.
     txid
           the transaction id as a hex string (little-endian as displayed by tools)
               Type str
     txout_index
          the index of the UTXO that we want to spend
               Type int
     script_sig
           the op code and data of the script as string
               Type list (strings)
     sequence
           the input sequence (for timelocks, RBF, etc.)
               Type bytes
     stream()
          converts TxInput to bytes
     copy()
          creates a copy of the object (classmethod)
     classmethod copy (txin)
          Deep copy of TxInput
     stream()
          Converts to bytes
class transactions.TxOutput (amount, script_pubkey)
     Represents a transaction output
     amount
           the value we want to send to this output (in BTC)
               Type float
     script_pubkey
           the script that will lock this amount
               Type list (string)
```

```
stream()
    converts TxInput to bytes

copy()
    creates a copy of the object (classmethod)

classmethod copy(txout)
    Deep copy of TxOutput

stream()
    Converts to bytes
```
